Fairbanks, Alaska 99709-3645

INTRODUCTION

Monitoring of interior Alaska streams affected by placer mining continued during the 1991 field season by Alaska Division of Water (DOW) (formerly the Water Section of the Division of Geological and Geophysical Surveys) investigators. The study, which began in 1984, is a combined effort of the Alaska Departments of Environmental Conservation (ADEC) and Fish and Game (**ADF&G**). Results of the previous field seasons can be found in Ray (1991), Ray (1990), Ray (1989), Mack et. al. (1988), Mack et al. (1987), Mack and Moorman (1987), and Mack and Moorman (1986).

Few changes were made in the 1991 field sampling plan. A water level recorder was added to the Deadwood Creek site to collect flow data with the sediment sampler added to the site in 1990. This site remains in the study plan since a high concentration of miners still exists upstream. An automatic sediment sampler and water level recorder were placed at Prospect Creek at the Dalton Highway. This site was added for comparison of streamflow and sediment data from a different hydrologic basin. Goldstream Creek at Ballaine Road site was moved to Standard Creek Road (approximately 15 miles downstream). An additional site on Goldstream Creek was added to the study at the Trans-Alaska Pipeline crossing near Fox. The upper Gold Dust Creek site was dropped from the study. The remaining sites were continued from the 1990 sampling season. These sites are Bear Creek, Birch Creek (above Twelve Mile Creek and at the Steese Highway bridge), Faith Creek, middle Gold Dust Creek and the Little Chena River at Chena Hot Springs Road. Flow data for the Little Chena River is provided by the US Geological Survey gage (US Geological Survey, 1992).

To ensure consistency of data between the different field seasons, the same sampling and analytical techniques were used during each field season. For details of the methods, see Mack et. al. (1988).

RESULTS

Discharge

Interior Alaska received record snowfall during the winter of 1990-91. Fairbanks received 147 inches, largest amount recorded since records began in 1906. The general snowpack over the study area was above normal. This heavy snowpack resulted in high stream flows during the month of May. This heavy snowpack also recharged the groundwater, resulting in declining **baseflow** discharge during the month of June. Little rain occurred during the months of June and July, resulting in low flows in most of the basins, but particularly those north of Eagle Summit. The largest precipitation event occurred *on* August 17-19, increasing flows at all sites. An additional storm on September 11-13 also caused increased flows. Figures 1 through 10 gives the hydrographs for the streams where discharge data was collected.

Turbidity

Mean turbidity remained nearly the same or increased slightly from previous years (see Tables 3-4). The two exceptions were Deadwood Creek and Birch Creek above Twelvemile Creeks. The mean and median turbidity at Deadwood Creek decreased, the median by a substantial amount (20 NTU in 1990 to 4.7 NTU in 1991). The mean turbidity at Birch Creek above Twelvemile Creek increased to levels similar to 1988, however the median turbidity was the lowest since the study began. The high mean turbidity was due to two events. The first event appears to be man-made, since there was no increase in flow. The daily mean turbidity for June 26 and 27 was 5200 and 3300 NTU, respectively. The second event was a storm event in August which caused a dramatic increase in flow, resulting in high sediment transport.

Total Suspended Sediment

Total suspended sediment (TSS) values at all sites except Birch Creek above Twelvemile Creek remained similar to or fell below 1990 values (Tables 5-6). The reason for the increase in TSS at Birch Creek above Twelvemile Creek is the same as the increase in turbidity as mentioned in the previous section.

Sediment Load

At most sites, the average daily sediment load (tons/day) was similar to recent years (Table 7). The average load at Faith Creek fell from 39 tons/day in 1990 to 6 tons/day in 1991. However, the average load at Birch Creek above Twelvemile Creek rose from 44 tons/day in 1990 to over 200 tons/day in 1991. The reasons for this rise are cited in previous sections.

Grab Sites

Data collected at the grab sites are reported in Table 8. Turbidity and TSS at most site decreased or remained similar to recent years. However, four sites experienced increasing sediment values. Both sites on Crooked Creek (below Bedrock Creek and at Steese Highway Bridge), **Ketchem** Creek, and Pedro Creek all had increased turbidity, some had increased TSS. Both Mammoth and Deadwood creeks continued to show decreased sediment values.
